Avalanche.report

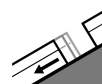

Danger Level 4 - High

Tendency: Decreasing avalanche danger
 on Sunday 17 03 2019

Wind-drifted
 snow

Gliding snow

A very precarious avalanche situation will persist. The fresh snow and wind slabs of yesterday remain prone to triggering. Increase in danger of wet and gliding avalanches as a consequence of warming during the day and solar radiation.

Restraint is advisable on this first sunny day. Much of the fresh and wind-drifted snow of Friday must be evaluated with care and prudence in all aspects above approximately 2200 m. Even single winter sport participants can release avalanches in many places, including large ones. In addition individual medium-sized to large natural dry avalanches are possible. As a consequence of warming during the day and the solar radiation, the likelihood of dry slab avalanches being released will increase a little. At elevated altitudes the prevalence and size of the avalanche prone locations will increase.
 Wet and gliding avalanches: A danger of gliding avalanches exists. This applies in particular on steep sunny slopes below approximately 2600 m as well as in all aspects below approximately 2200 m. In particular here individual occasionally large gliding avalanches are possible. In addition as the day progresses numerous small and medium-sized moist loose snow avalanches are to be expected. This applies on extremely steep sunny slopes in all altitude zones.

Snowpack

Danger patterns

dp 6: cold, loose snow and wind

dp 2: gliding snow

Over a wide area 40 to 80 cm of snow, and even more in some localities, has fallen in the last two days above approximately 2000 m. The wind was strong to storm force. Fresh snow and wind slabs are lying mostly on the soft surface of an old snowpack, in particular above approximately 2200 m. The various wind slabs have bonded poorly with each other and the old snowpack. The old snowpack will be stable over a wide area. The snowpack will be wet all the way through at low and intermediate altitudes. The snowpack will become moist on sunny slopes.

Tendency

Considerable avalanche danger will prevail.

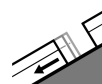

Danger Level 3 - Considerable

Tendency: Constant avalanche danger →

Gliding snow

The fresh snow and wind slabs of yesterday remain prone to triggering above approximately 2200 m. Increase in danger of wet and gliding avalanches as a consequence of warming during the day and solar radiation.

Restraint is advisable on this first sunny day. Much of the fresh and wind-drifted snow of Friday must be evaluated with care and prudence in all aspects above approximately 2200 m. Even single winter sport participants can release avalanches in many places, including dangerously large ones. Caution is to be exercised in particular at transitions from a shallow to a deep snowpack, when entering gullies and bowls for example as well as in places that are protected from the wind. In addition further individual medium-sized to large natural dry avalanches are possible. As a consequence of warming during the day and the solar radiation, the likelihood of slab avalanches being released will increase a little.
 Wet and gliding avalanches:
 A danger of gliding avalanches exists. This applies in particular on steep sunny slopes below approximately 2600 m as well as in all aspects below approximately 2200 m. Individual gliding avalanches are possible, even large ones in isolated cases. In particular, however, as the day progresses numerous small and medium-sized moist loose snow avalanches are to be expected. This applies on extremely steep sunny slopes in all altitude zones.

Snowpack

Danger patterns

dp 6: cold, loose snow and wind

dp 2: gliding snow

30 to 60 cm of snow, and even more in some localities, has fallen in the last two days above approximately 2000 m. The wind was strong to storm force. Fresh snow and wind slabs are lying mostly on the soft surface of an old snowpack, in particular above approximately 2200 m. Wind slabs are bonding only slowly with the old snowpack. The old snowpack will be stable over a wide area. The snowpack will be wet all the way through at low and intermediate altitudes. The snowpack will become moist on sunny slopes.

Tendency

Considerable avalanche danger will prevail.

Danger Level 2 - Moderate

Tendency: Constant avalanche danger →
on Sunday 17 03 2019

Wind-drifted
snow

Treeline

Fresh wind slabs represent the main danger.

As a consequence of fresh snow and a sometimes strong wind from westerly directions, avalanche prone wind slabs formed in the last few days. The fresh wind slabs can in some places be released, even by a single winter sport participant and reach medium size. The avalanche prone locations are to be found on northwest to north to east facing aspects at high altitudes and in high Alpine regions, especially in gullies and bowls, and behind abrupt changes in the terrain. As a consequence of warming during the day and the solar radiation, the likelihood of slab avalanches being released will increase a little. In addition as the day progresses numerous mostly small moist loose snow avalanches are to be expected. This applies on extremely steep sunny slopes in all altitude zones.

Snowpack

Danger patterns

dp 6: cold, loose snow and wind

10 to 20 cm of snow, and even more in some localities, has fallen in the last two days above approximately 2000 m. The wind was strong in some cases. Wind slabs are lying on soft layers in particular on steep shady slopes above the tree line. The old snowpack will be quite stable. The snowpack will be wet all the way through at low altitude. The snowpack will become increasingly moist.

Tendency

Moderate avalanche danger will prevail.

Danger Level 1 - Low

Tendency: Constant avalanche danger →
on Sunday 17 03 2019

Wind-drifted
snow

2200m

A quite favourable avalanche situation will be encountered over a wide area. Fresh wind slabs represent the main danger.

As a consequence of a moderate to strong wind from westerly directions, sometimes avalanche prone wind slabs formed in the last few days especially adjacent to ridgelines and in pass areas. The fresh wind slabs can in isolated cases be released by a single winter sport participant, but they will be small in most cases. The avalanche prone locations are to be found on northwest to north to northeast facing aspects above approximately 2200 m. These places are rare and are clearly recognisable to the trained eye. As a consequence of warming during the day and the solar radiation, the likelihood of moist loose snow avalanches being released will increase a little on extremely steep sunny slopes.

Snowpack

Danger patterns

dp 6: cold, loose snow and wind

Up to 10 cm of snow. fell above approximately 2000 m. The wind was moderate to strong. Fresh wind slabs are mostly only small. The old snowpack will be quite stable. Individual weak layers exist in the bottom section of the old snowpack on shady slopes, in particular in areas close to the tree line in little used backcountry terrain. The snowpack will become moist on sunny slopes.

Tendency

The conditions are quite favourable.
