

## Danger Level 2 - Moderate

**Tendency: Constant avalanche danger** →  
 on Tuesday 20 12 2022

Persistent weak layer

Wet snow

Snowpack stability: **poor**  
 Frequency: **some**  
 Avalanche size: **medium**

Snowpack stability: **poor**  
 Frequency: **some**  
 Avalanche size: **small**

Wind slabs and weakly bonded old snow are to be critically assessed. As the day progresses as a consequence of warming there will be a gradual increase in the danger of wet and gliding avalanches.

Weak layers in the old snowpack can be released in some places by individual winter sport participants. The avalanche prone locations are to be found in particular on very steep west, north and east facing slopes above approximately 2000 m and on very steep sunny slopes below approximately 2500 m. The wind slabs of the last few days can be released by a single winter sport participant in some cases in particular on near-ridge shady slopes at elevated altitudes. Individual medium-sized avalanches are possible. Meticulous route selection is advisable.

As a consequence of warming more frequent gliding avalanches and moist snow slides are to be expected as the day progresses, but they will be mostly small. This applies in particular on very steep sunny slopes, as well as on cut and grassy slopes at low and intermediate altitudes.

### Snowpack

**Danger patterns**

dp.1: deep persistent weak layer

dp.2: gliding snow

The new snow and wind slabs of the last few days are lying on top of a weakly bonded old snowpack. This applies in particular on very steep shady slopes above approximately 2000 m, as well as on very steep sunny slopes above approximately 2500 m.

The spring-like weather conditions as the day progresses will give rise to a loss of strength within the snowpack over a wide area especially at intermediate altitudes.

Only a small amount of snow is lying for the time of year.

### Tendency

Wind slabs and weakly bonded old snow at high altitude.

Mostly small moist snow slides and avalanches are to be expected as a consequence of warming.

## Danger Level 2 - Moderate

**Tendency: Constant avalanche danger** →  
 on Tuesday 20 12 2022

Persistent weak layer

Snowpack stability: **poor**  
 Frequency: **some**  
 Avalanche size: **medium**

### Weakly bonded old snow represents the main danger.

Weak layers in the old snowpack can be released in some places by individual winter sport participants. The avalanche prone locations are to be found in particular on steep west, north and east facing slopes above approximately 2000 m, especially in shady places that are protected from the wind. Avalanches can reach medium size. Isolated whumpfung sounds can indicate the danger. Meticulous route selection is recommended.

In addition the mostly small wind slabs are prone to triggering in isolated cases still. Caution is to be exercised adjacent to ridgelines and in pass areas on very steep north and east facing slopes at high altitudes and in high Alpine regions. At elevated altitudes the avalanche prone locations are a little more prevalent.

As a consequence of warming small moist loose snow avalanches are to be expected. This applies on extremely steep sunny slopes, as well as on cut and grassy slopes especially at low and intermediate altitudes.

On steep grassy slopes more frequent gliding avalanches are possible, but they will be mostly small.

### Snowpack

**Danger patterns**

dp.1: deep persistent weak layer

dp.2: gliding snow

Avalanche prone weak layers exist in the old snowpack, especially on steep shady slopes above approximately 2000 m, as well as on steep sunny slopes in high Alpine regions. Released avalanches and field observations confirm the unfavourable bonding of the snowpack.

As a consequence of new snow and a moderate wind, mostly small wind slabs formed adjacent to ridgelines and in pass areas. They are in some cases still prone to triggering especially on very steep shady slopes at elevated altitudes. As a consequence of rising temperatures the snow drift accumulations will stabilise during the next few days.

Sunshine and high temperatures will give rise as the day progresses to gradual moistening of the snowpack in particular on sunny slopes at low and intermediate altitudes.

### Tendency

Tuesday: The old snowpack remains prone to triggering on shady slopes. Even single winter sport participants can release avalanches in some places, including dangerously large ones.

## Danger Level 2 - Moderate

**Tendency: Constant avalanche danger** →  
on Tuesday 20 12 2022

Persistent  
weak layer

Snowpack stability: **poor**  
Frequency: **few**  
Avalanche size: **medium**

Weak layers in the old snowpack can be released in isolated cases on shady slopes.

Weak layers in the old snowpack can be released in isolated cases by individual winter sport participants. The avalanche prone locations are to be found in particular on very steep shady slopes above approximately 2000 m, especially at the base of rock walls and behind abrupt changes in the terrain, as well as on wind-loaded slopes. Here medium-sized avalanches are possible.

In addition the small wind slabs are prone to triggering in very isolated cases still. Avalanche prone locations are to be found in particular on north and east facing slopes at elevated altitudes. Wind slabs are to be avoided in particular in terrain where there is a danger of falling.

As a consequence of warming small moist loose snow avalanches are to be expected. This applies on extremely steep sunny slopes, as well as on cut and grassy slopes especially at low and intermediate altitudes.

On steep grassy slopes more frequent gliding avalanches are possible, but they will be mostly small.

### Snowpack

#### Danger patterns

dp.1: deep persistent weak layer

dp.2: gliding snow

Avalanche prone weak layers exist in the old snowpack, especially on very steep shady slopes above approximately 2000 m, as well as on sunny slopes in high Alpine regions.

As a consequence of new snow and a moderate wind, small wind slabs formed adjacent to ridgelines and in pass areas. They are in individual cases still prone to triggering on very steep shady slopes at elevated altitudes. As a consequence of rising temperatures the snow drift accumulations will stabilise.

Sunshine and high temperatures will give rise as the day progresses to gradual moistening of the snowpack in particular on sunny slopes at low and intermediate altitudes.

### Tendency

Tuesday: The old snowpack remains prone to triggering in some places.
