

Danger Level 4 - High

Tendency: Constant avalanche danger →
 on Sunday 25 12 2022

Persistent weak layer

Snowpack stability: **poor**
 Frequency: **many**
 Avalanche size: **large**

New snow

Snowpack stability: **poor**
 Frequency: **many**
 Avalanche size: **medium**

Wet snow

Snowpack stability: **very poor**
 Frequency: **many**
 Avalanche size: **small**

For those venturing off piste a precarious avalanche situation will prevail.

The danger exists primarily in alpine snow sports terrain. As a consequence of mild temperatures, snowfall above approximately 2200 m and the strong to storm force northwesterly wind, a precarious avalanche situation will develop on Christmas Day.

Even single freeriders can release avalanches in many places. Avalanches can penetrate down to the ground and reach quite a large size especially in the regions with a lot of snow, especially on shady slopes above approximately 2200 m, and on sunny slopes above approximately 2400 m. Caution is to be exercised in particular adjacent to ridgelines, as well as in gullies and bowls, and behind abrupt changes in the terrain. The avalanche prone locations are difficult to recognise. Remotely triggered avalanches are possible. Great caution and restraint are required.

In addition natural avalanches are possible. This applies in all aspects at high altitudes and in high Alpine regions.

All aspects below approximately 2200 m: As the penetration by moisture increases more moist and wet snow slides are possible.

Snowpack

Danger patterns

dp.1: deep persistent weak layer

dp.3: rain

In particular in the north and in the west over a wide area 30 to 50 cm of snow, and even more in some localities, will fall until Saturday above approximately 2200 m. As a consequence of new snow and a sometimes storm force wind from northwesterly directions, extensive wind slabs will form. These will be deposited on a weakly bonded old snowpack in particular on west to north to east facing aspects above approximately 2200 m. The various wind slabs have bonded poorly together.

The rain will give rise to gradual and thorough wetting of the snowpack over a wide area below approximately 2200 m.

Tendency

Sunday: Outside marked and open pistes a precarious avalanche situation will persist. Restraint is advisable on this first sunny day.

Danger Level 3 - Considerable

Tendency: Constant avalanche danger →
 on Sunday 25 12 2022

Persistent weak layer

Snowpack stability: **poor**
 Frequency: **some**
 Avalanche size: **large**

Wind slab

Snowpack stability: **poor**
 Frequency: **some**
 Avalanche size: **medium**

Wet snow

Snowpack stability: **very poor**
 Frequency: **some**
 Avalanche size: **small**

Wind slabs and weakly bonded old snow represent the main danger.

As a consequence of mild temperatures, snowfall above approximately 2200 m and the strong to storm force northwesterly wind, a sometimes precarious avalanche situation will develop on Christmas Day. Even single winter sport participants can release avalanches easily, in particular on steep west, north and east facing slopes above approximately 2200 m, as well as on very steep sunny slopes at elevated altitudes. Avalanches can in some cases penetrate deep layers and reach large size. Caution is to be exercised in particular adjacent to ridgelines, as well as in gullies and bowls, and behind abrupt changes in the terrain. The avalanche prone locations are difficult to recognise. Caution and restraint are required.

As the snowfall level rises gliding avalanches and moist snow slides are possible below approximately 2200 m. This applies in particular on the Main Alpine Ridge and to the north.

Snowpack

Danger patterns

dp.1: deep persistent weak layer

In some localities up to 15 cm of snow will fall until Saturday above approximately 2200 m. In the south less snow will fall. Some fresh snow as well as the mostly small wind slabs that are being formed by the strong to storm force northwesterly wind are prone to triggering. The fresh wind slabs will be deposited on a weakly bonded old snowpack in particular on steep shady slopes above approximately 2200 m. The various wind slabs have bonded poorly with each other and the old snowpack. Towards its base, the snowpack is faceted and weak.

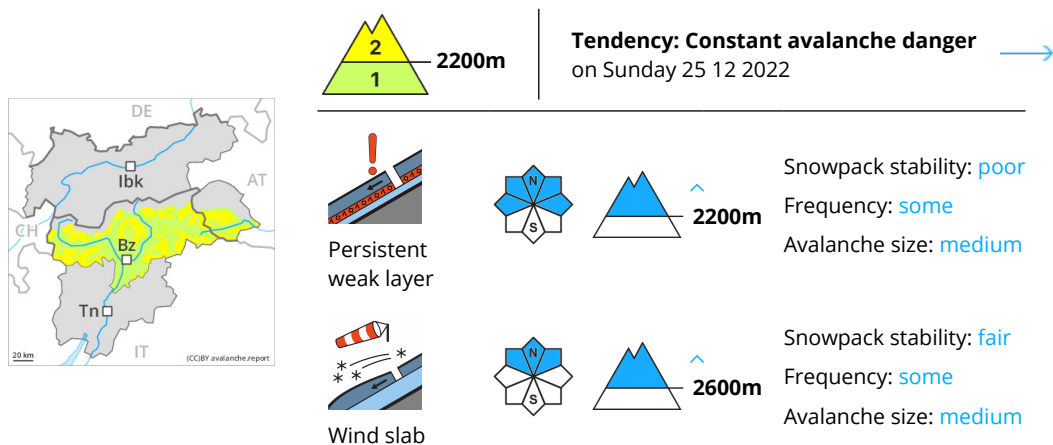

The rain will give rise to gradual and thorough wetting of the snowpack over a wide area below approximately 2200 m.

Tendency

Wind slabs and weakly bonded old snow represent the main danger. Sunday: Restraint is advisable on this first sunny day.

Danger Level 2 - Moderate

Weak layers in the old snowpack represent the main danger.

In some places avalanches can be triggered in the weakly bonded old snow, in particular on very steep west, north and east facing slopes above approximately 2200 m, as well as on very steep sunny slopes at elevated altitudes. Avalanches can in isolated cases reach medium size. As a consequence of a strong to storm force wind from northwesterly directions, mostly small wind slabs will form on Christmas Day. They are to be evaluated with care and prudence in steep terrain. Caution is to be exercised adjacent to ridgelines and in pass areas, as well as at elevated altitudes. In the regions neighbouring those that are subject to danger level 3 (considerable) the avalanche danger is a little higher.

Snowpack

Danger patterns

dp.1: deep persistent weak layer

Towards its base, the snowpack is faceted and weak, especially on steep west, north and east facing slopes above approximately 2200 m, as well as on steep sunny slopes at elevated altitudes.

Over a wide area strong northwesterly wind. The fresh wind slabs will be deposited on soft layers in particular on shady slopes above approximately 2600 m.

In the north a little snow is lying.

Tendency

Wind slabs and weakly bonded old snow are to be assessed with care and prudence.

Danger Level 2 - Moderate

Tendency: Constant avalanche danger →
 on Sunday 25 12 2022

Persistent weak layer

Snowpack stability: **poor**
 Frequency: **some**
 Avalanche size: **medium**

Wet snow

Snowpack stability: **poor**
 Frequency: **few**
 Avalanche size: **medium**

Wind slab

Snowpack stability: **fair**
 Frequency: **some**
 Avalanche size: **medium**

Weak layers in the old snowpack represent the main danger.

Weak layers in the old snowpack can still be released by individual winter sport participants. This applies in particular on very steep west, north and east facing slopes above approximately 2200 m, as well as on very steep sunny slopes at elevated altitudes. Caution is to be exercised adjacent to ridgelines, as well as in gullies and bowls, and behind abrupt changes in the terrain. Avalanches can in isolated cases reach medium size.

Below approximately 2600 m moist small and medium sized avalanches are possible. As a consequence of a sometimes strong wind from northwesterly directions, rather small wind slabs will form in the course of the day. Caution is to be exercised in particular on very steep shady slopes above approximately 2800 m adjacent to ridgelines.

Meticulous route selection is recommended.

Snowpack

Danger patterns

dp.1: deep persistent weak layer

Towards its base, the snowpack is faceted and weak, especially on steep west, north and east facing slopes above approximately 2200 m. Released avalanches and field observations confirm the unfavourable bonding of the snowpack. The fresh wind slabs will be deposited on soft layers in particular on northwest, north and northeast facing slopes above approximately 2800 m.

As a consequence of mild temperatures a crust formed on the surface during the last few days. This applies in particular on steep sunny slopes below approximately 2600 m.

Tendency

The old snowpack remains prone to triggering. As a consequence of warming during the day and solar

radiation more small and medium-sized moist snow slides and avalanches are possible.
